

Guide to WEB1 documentation in SEP1

When you document the development of your website, you should only document the final version of your website. This document is a guide to which parts of your website should be described/documented in your SEP1 report. The examples provided in this document is only to illustrate what is expected in the documentation and the level of detail that is needed. As you can see, the website should be included in all chapters of the SEP1 report.

Analysis

There may be both functional and non-functional requirements to the website. You should check the description of the website to see if there are any of the requirements that should be included in the functional and/or non-functional requirements (*HINT: there is at least one*).

Functional requirements

An example of functional requirements for the website may be:
The website needs to display information from...

You may also come up with other functional requirements that you want to implement.

Non-functional requirements

An example of a non-functional requirement for the website may be:
The XXX needs to be in YYY format...
The website must be implemented in...

But it could also include requirements to layout, colors, and the user experience.

Use case diagram

Make sure that you have the functional requirements for the website in your use case diagram as well.

Figure 1: Use case diagram.

Use case description and activity diagrams

If you have use case descriptions and activity diagrams for the website, they should be in the Appendix.

Design

Document/describe your Java application first and then have a subchapter for the website.

Website

Make a short description of the website and the purpose of the website.

Example (look in your case description and rewrite the description – in the example shown below, the text is not rewritten (much)):

The website for ColourIT should be a web access to the customers. On this website, the customers may find information about their projects like a short description of the project and then a table displaying all the requirements for the project, deadlines etc. Further, blahblahblah.....

Discuss the layout of the website, i.e. thoughts and considerations that you had when you decided the position/sizing/color etc of elements on the website, both for the desktop and mobile versions. Include wireframes (maybe not for all parts of your website, but at least for the frontpages of both the desktop and mobile versions) to illustrate how the layout should be.

Example:

The desktop layout was kept simple by...

The mobile layout rearranged the elements and some elements were hidden to keep the layout simple....

The color palette was chosen by using the <https://coolers.co/> website...

The font type chosen for the website was...

Figure 2: wireframes illustrating the layout of both desktop and mobile version of website.

Implementation

Again, document everything about your Java application first and then the website (to keep it consistent).

Website

Describe how (interesting) parts of your website were implemented.

Content and presentation layers

Start with the content and presentation layers (HTML5 and CSS3) and include both code and a screenshot (where it makes sense and is interesting for the reader to see).

Example

The HTML and CSS code illustrated in Figure 3 below, illustrates how the XXX part of the website was implemented. On line X in the HTML code, the Y element is defined with the Z attribute(s). The Y element is then styled with the ??? properties and values in the CSS code, where the *property* sets the XX of the element to *value*....

HTML:

```
1 <!DOCTYPE html>
2 <html>
3   <head>
4     <meta charset="UTF-8">
5     <title>Title goes here</title>
6   </head>
7   <body>
8
9   </body>
10 </html>
```

CSS:

```
.links__item {
  display: block;
  max-width: 550px;
  margin: 0 auto 15px;
  margin-bottom: 5px;
  padding: 15px 20px;
  font-size: 0.95rem;
  line-height: 1.5;
  text-decoration: none;
  transition: all 0.2s ease-in-out;
  color: black;
}
```

Figure 3: HTML and CSS code (for illustration purposes only - this does not reflect what is shown in the screenshot of the website in the figure below).

Desktop:

Mobile:

Figure 4: Desktop and mobile layouts that is the result of the HTML and CSS code in the figure above.

Behavior layer

Once you have documented the interesting parts of the content and presentation layers, you can document the behavior layer (JavaScript) – here you only need the code snippets, but remember to explain everything that goes on in the code.

```
$(document).ready(function() {
    changeColor();
});

function changeColor() {
    var rndColors = ["#00FF00", "#CCCCCC", "#995499", "#FFFFFF", "#FF9900"];
    var selColor = Math.floor(Math.random() * rndColors.length);
    $('div').css("background-color", rndColors[selColor]);
    setTimeout(changeColor, 1000);
}
```

Figure 5: JavaScript code snippet of something interesting/important in your implementation.

Example:

In the JavaScript code snippet in Figure 5, a function `changeColor()` is declared starting with a declaration of an array variable containing five different hex colors. The next variable that is declared selects one of these five colors by using the `Math.floor()` and `Math.random()` global functions in JavaScript. The `changeColor()` function is called each time the HTML document is loaded which means that it will have a different color every time a user loads the webpage.

Test

You should also test the functional requirements for the website and document the outcome in the test chapter of your SEP1 report.

Use case	Test case	Result
Website import of external file	XML file placed on webserver....	The data is imported correctly and displayed on the website.
